Christian Hennig Some thoughts about robust clustering

・ロン ・回 と ・ 回 と ・ 回 と

## 1. Introduction

Nonrobustness of mean/covariance matrix-based methods well known.

Done by Gaussian mixture ML clustering:

$$f(\mathbf{x}) = \sum_{i=1}^{s} \pi_i \varphi_{\mathbf{a}_i, \Sigma_i}(\mathbf{x}).$$

◆□ > ◆□ > ◆臣 > ◆臣 > ○臣 ○ のへで

Done by Gaussian mixture ML clustering:

$$f(\mathbf{x}) = \sum_{i=1}^{s} \pi_i \varphi_{\mathbf{a}_i, \boldsymbol{\Sigma}_i}(\mathbf{x}).$$

Number of components can be estimated by BIC (*s* = 2 here). Various covariance matrix models (free, all equal, spherical...). Given the estimated parameters, points can be classified by max.  $\hat{P}(\gamma = j | \mathbf{x}) = (\hat{\pi}_j \varphi_{\hat{\mathbf{a}}_j, \hat{\Sigma}_j}(\mathbf{x})) / (\sum_{i=1}^k \hat{\pi}_i \varphi_{\hat{\mathbf{a}}_i, \hat{\Sigma}_i}(\mathbf{x}))$  Software R-package mclust (Fraley and Raftery).

Similar robustness problems for *k*-means, other methods.

Improper noise (Hennig 2004, Coretto 2008)

$$f(\mathbf{x}) = \pi_0 \mathbf{c} + \sum_{j=1}^{s} \pi_j \varphi_{\mathbf{a}_j, \Sigma_j}(\mathbf{x}),$$

► Trimmed likelihood (Neykov, Filzmoser, Dimova, Neytchev 2007)

Mixture models Fixed partition models Finding outlier free data subsets How the methods do

### 2.2 Fixed Partition Models

$$f(\mathbf{x}_1,\ldots,\mathbf{x}_n)=\prod_{i=1}^n \varphi_{\mathbf{a}_{\gamma(i)},\boldsymbol{\Sigma}_{\gamma(i)}}(\mathbf{x}_i),$$

 $\gamma$  :  $\{1, \ldots, n\} \rightarrow \{1, \ldots, s\}$ . *k*-means is a fixed partition ML-method (equal spherical covariance matrices).

・ロト ・回ト ・ヨト ・ヨト - 三

Mixture models Fixed partition models Finding outlier free data subsets How the methods do

### 2.2 Fixed Partition Models

$$f(\mathbf{x}_1,\ldots,\mathbf{x}_n)=\prod_{i=1}^n\varphi_{\mathbf{a}_{\gamma(i)},\boldsymbol{\Sigma}_{\gamma(i)}}(\mathbf{x}_i),$$

 $\gamma: \{1, \ldots, n\} \rightarrow \{1, \ldots, s\}.$ *k*-means is a fixed partition ML-method (equal spherical covariance matrices). Crisp assignment of points, inconsistent for parameter estimation, but often good for classification.

Mixture models Fixed partition models Finding outlier free data subsets How the methods do

# **Robustification:**

 Replacing mean/covariance matrix by robust estimators (medians, MCD) (Kaufman & Rousseeuw 1990, Rocke & Hardin 2000)

Mixture models Fixed partition models Finding outlier free data subsets How the methods do

# **Robustification:**

- Replacing mean/covariance matrix by robust estimators (medians, MCD)
   (Kaufman & Rousseeuw 1990, Rocke & Hardin 2000)
- Trimming: optimise ML-criterion for best n r points.
   α-trimmed k-means
   (Cuesta-Albertos, Gordaliza, Matran 1997)
- Equal covariance matrices (Gallegos & Ritter 2005)
- Flexible covariance matrices (Garcia-Escudero, Gordaliza, Matran, Mayo-Iscar 2008)

- Fixed point clusters (Hennig & Christlieb 2002)
- Forward search (Atkinson, Cerioli & Riani 2003)

・ロン ・回 と ・ ヨン・

Mixture models Fixed partition models Finding outlier free data subsets How the methods do

How the methods do (with s = 2)

- Outlier only "noise point" (proper choice of c)
- t-mixtures integrate it with cluster 1.
- Trimming: will be trimmed.
   Need flexible covarince matrices, proper trimming rate.

Breakdown theory for mixtures The dissolution point

# 3. Breakdown and robustness measurement3.1 Breakdown theory for mixtures (Hennig 2004)

Finite sample addition **breakdown point** (Donoho and Huber 1983): smallest possible contamination  $(\frac{g}{n+g})$  to be added to the dataset so that estimator becomes "arbitrarily bad".

イロト イヨト イヨト イヨト

-2

**Definition 1.** Be 
$$\hat{\theta}_{n,s}$$
:  $\mathbf{x}_n \rightarrow \theta \in \Theta$  estimator, where

$$\Theta = \{(\pi_1, \ldots, \pi_s, \boldsymbol{a}_1, \ldots, \boldsymbol{a}_s, \sigma_1, \ldots, \sigma_s): \sum \pi_j = 1, \ \sigma_j \ge \boldsymbol{c} > \boldsymbol{0} \forall j \}.$$

For g > 0 let

 $Y_g(\mathbf{x}_n) = \{\mathbf{x}_{n+g} \in I\!\!R^{n+g} : \text{ first n observations equal } \mathbf{x}_n\}$ 

**Breakdown point**  $\hat{\theta}_{\bullet,s}$ :  $B(\hat{\theta}_{\bullet,s}, \mathbf{x}_n) = \min \frac{g}{n+g}$  so that at least one of the following for at least one  $i \in \{1, \dots, s\}$ :

• 
$$\inf_{\mathbf{x}_{n+g}\in Y_g(\mathbf{x}_n)} \hat{\pi}_i(\mathbf{x}_{n+g}) = 0$$
 for  $i$  with  $\hat{\pi}_i(\mathbf{x}_n) > 0$ ,

• 
$$\sup_{\mathbf{x}_{n+g}\in Y_g(\mathbf{x}_n)} \hat{\sigma}_i(\mathbf{x}_{n+g}) = \infty$$

► 
$$\sup_{\mathbf{x}_{n+g}\in Y_g(\mathbf{x}_n)} |\hat{\mathbf{a}}_i(\mathbf{x}_{n+g})| = \infty.$$

◆□▶ ◆□▶ ◆三▶ ◆三▶ ◆□▶

Breakdown theory for mixtures The dissolution point

Theorem 2. Let s > 1,  $\hat{\theta}_{n,s}(\mathbf{x}_n) = \operatorname*{arg\,max}_{\theta \in \Theta} L_{n,s}(\theta, \mathbf{x}_n),$  $L_{n,s}(\theta, \mathbf{x}_n) = \sum_{i=1}^n \log\left(\sum_{j=1}^s \pi_j \varphi_{\mathbf{a}_j, \sigma_j}(x_i)\right),$ 

the ML-estimator. Then  $B(\hat{\theta}_{\bullet,s}, \mathbf{x}_n) = \frac{1}{n+1}$ .

・ロン ・回 と ・ 回 と ・ 回 と

-

Breakdown theory for mixtures The dissolution point

.

◆ロ〉 ◆御〉 ◆臣〉 ◆臣〉 「臣」 のへで

$$L_{n,s}(\eta) = \sum_{i=1}^{n} \log \left( \sum_{j=1}^{s} \pi_j f_{\mathbf{a}_j,\sigma_j}(\mathbf{x}_i) \right) + \log \left( \sum_{j=1}^{s} \pi_j f_{\mathbf{a}_j,\sigma_j}(\mathbf{x}_{n+1}) \right)$$

Breakdown theory for mixtures The dissolution point

.

◆ロ〉 ◆御〉 ◆臣〉 ◆臣〉 「臣」 のへで

$$L_{n,s}(\eta) = \sum_{i=1}^{n} \log \left( \sum_{j=1}^{s} \pi_j f_{\mathbf{a}_j,\sigma_j}(\mathbf{x}_i) \right) + \log \left( \sum_{j=1}^{s} \pi_j f_{\mathbf{a}_j,\sigma_j}(\mathbf{x}_{n+1}) \right)$$

Breakdown theory for mixtures The dissolution point

.

◆ロ〉 ◆御〉 ◆臣〉 ◆臣〉 「臣」 のへで

$$L_{n,s}(\eta) = \sum_{i=1}^{n} \log \left( \sum_{j=1}^{s} \pi_j f_{\mathbf{a}_j,\sigma_j}(\mathbf{x}_i) \right) + \log \left( \sum_{j=1}^{s} \pi_j f_{\mathbf{a}_j,\sigma_j}(\mathbf{x}_{n+1}) \right)$$

Breakdown theory for mixtures The dissolution point

$$L_{n,s}(\eta) = \sum_{i=1}^{n} \log \left( \sum_{j=1}^{s} \pi_j f_{\mathbf{a}_j,\sigma_j}(\mathbf{x}_i) \right) + \log \left( \sum_{j=1}^{s} \pi_j f_{\mathbf{a}_j,\sigma_j}(\mathbf{x}_{n+1}) \right)$$

No breakdown of original components:

$$\mathbf{x}_{n+1} 
ightarrow \infty \Rightarrow L_{n,s} 
ightarrow -\infty$$
 is a first the second second

Breakdown theory for mixtures The dissolution point

$$a_s = x_{n+1} \Rightarrow L_{n,s} \ge \text{const}$$
, thus  $B = \frac{1}{n+1}$ 

(as well for t-mixtures and  $\frac{1}{V}$ -noise component)

Breakdown theory for mixtures The dissolution point

### Improper noise:

$$\hat{\eta}_{n,s} = rg\max_{\eta} \sum_{i=1}^{n} \log\left(\sum_{j=1}^{s} \pi_j f_{a_j,\sigma_j}(x_i) + \pi_0 c\right)$$

### with fixed c

◆□ > ◆□ > ◆臣 > ◆臣 > ○臣 ○ のへで

Breakdown theory for mixtures The dissolution point

Theorem 3.  

$$\forall r < s : (\hat{L}_{n,s} - \hat{L}_{n,r}) >$$
  
 $n \log \frac{cg}{n} + g \log((\pi_0 + \frac{g}{n})c) + (n+g) \log \frac{n}{n+g} - g \log f_{max}$   
 $\Rightarrow B_n > \frac{g}{n+g}$  (data dependent)

Breakdown theory for mixtures The dissolution point

Theorem 3.  

$$\forall r < s : (\hat{L}_{n,s} - \hat{L}_{n,r}) >$$
  
 $n \log \frac{cg}{n} + g \log((\pi_0 + \frac{g}{n})c) + (n+g) \log \frac{n}{n+g} - g \log f_{max}$   
 $\Rightarrow B_n > \frac{g}{n+g}$  (data dependent)

**Trimming:** Gallegos & Ritter (2005) have data dependent breakdown point under separation condition, too. Garcia-Escudero & Gordaliza (1999) know that it's data dependent.

イロト イヨト イヨト イヨト

-2

Breakdown theory for mixtures The dissolution point

### 3.2 The dissolution point (Hennig 2008)

Clusters may break down without parameters breaking down. Some clustering methods don't estimate parameters.

Breakdown theory for mixtures The dissolution point

# **Aim: "something like" a breakdown point** for general clustering methods (GCM):

$$egin{aligned} & E = (E_n)_{n \in \mathbb{N}}, \ & E_n: \ \mathbf{x}_n \mapsto \{C_1, \dots, C_k\}, \ C_j \subseteq \mathbf{x}_n. \end{aligned}$$

(Assume  $C_i \cap C_j = \emptyset$ .)

Wanted: results in terms of set memberships, not parameters.

・ロト ・回ト ・ヨト ・ヨト - 三

Breakdown theory for mixtures The dissolution point

Induced clustering (g points added):

$$E_n^*(\mathbf{x}_{n+g}) = E_{n+g}(\mathbf{x}_{n+g}) \cap \mathbf{x}_n$$

Cluster similarity (Jaccard, 1901):

$$\gamma(\mathbf{C}, \mathbf{D}) = rac{|\mathbf{C} \cap \mathbf{D}|}{|\mathbf{C} \cup \mathbf{D}|}, \ \gamma^*(\mathbf{C}, \mathcal{D}) = \max_{\mathbf{D} \in \mathcal{D}} \gamma(\mathbf{C}, \mathbf{D}).$$

**Principle:** A cluster is **dissolved** if the closest cluster in induced clustering (under addition) is too far away. (How far is "too far"?)

・ロン ・回 と ・ ヨン・

-2

Breakdown theory for mixtures The dissolution point

**Definition 4.** 

$$\Delta(\boldsymbol{E}, \mathbf{x}_n, \boldsymbol{C}) = \min_g \\ \left\{ \frac{g}{|\boldsymbol{C}|+g} : \exists \mathbf{x}_{n+g} = (x_1, \dots, x_{n+g}) : \\ \gamma^*(\boldsymbol{C}, \boldsymbol{E}_n^*(\mathbf{x}_{n+g})) \leq \frac{1}{2} \right\}$$

is called **dissolution point** of cluster C.

1/2 not worst possible value, but...

・ロン ・回 と ・ 回 と ・ 回 と

Breakdown theory for mixtures The dissolution point

**Definition 4.** 

$$\Delta(E, \mathbf{x}_n, C) = \min_g \left\{ \frac{g}{|C|+g} : \exists \mathbf{x}_{n+g} = (\mathbf{x}_1, \dots, \mathbf{x}_{n+g}) : \gamma^*(C, E_n^*(\mathbf{x}_{n+g})) \leq \frac{1}{2} \right\}$$

is called **dissolution point** of cluster C.

1/2 not worst possible value, but...

- $\blacktriangleright \frac{1}{2}$  is minimal such that
  - for  $n \ge 2$ ,  $k \ge 2$ , every cluster can dissolve,
  - ▶ whenever |C| = s, |D\*| = s − r, at least r members of C dissolve.

・ロン ・回 と ・ 回 と ・ 回 と

-

Breakdown theory for mixtures The dissolution point

### Example of a dissolution result

**Theorem 5.** Let  $E_k$  be  $\alpha$ -trimmed *k*-means clustering. For  $g \le n - \lceil n(1 - \alpha) \rceil$ , if for any possible induced clustering  $C^*$  leading to dissolution of *C*:

$$\begin{split} \min_{y_1,\dots,y_g\in D(E_{k,n}(\mathbf{x}_n))} \sum_{i=1}^g \min_j \|y_i - \bar{x}_j\|_2^2 \\ < Q(\mathbf{x}_n,\mathcal{C}^*) - Q(\mathbf{x}_n,E_{k,n}(\mathbf{x}_n)), \end{split}$$
then  $\Delta(E_k,\mathbf{x}_n,C) > \frac{g}{|C|+g}. \end{split}$ 

・ロン ・四 ・ ・ ヨン ・ ヨン

### 4. Estimated s (by BIC; Hennig 2004)

**Definition 6.** Let  $\hat{\theta}_n : \mathbf{x}_n \to \theta \in \Theta_*, \Theta_* \text{ as } \Theta \text{ in Definition 1 but with parameter } s \in \mathbb{N}$ . The **breakdown point** of estimator  $\hat{\theta}_{\bullet}$  is  $B(\hat{\theta}_{\bullet}, \mathbf{x}_n) = \min \frac{g}{n+g}$  so that  $\inf_{\mathbf{x}_{n+g} \in Y_g(\mathbf{x}_n)} \hat{\mathbf{s}}(\mathbf{x}_{n+g}) < \hat{\mathbf{s}}(\mathbf{x}_n)$ , or at least one of the following for at least one  $i \in \{1, \dots, \hat{\mathbf{s}}(\mathbf{x}_n)\}$ :  $\blacktriangleright \inf_{\mathbf{x}_{n+g} \in Y_g(\mathbf{x}_n)} \hat{\pi}_i(\mathbf{x}_{n+g}) = 0$  for i with  $\hat{\pi}_i(\mathbf{x}_n) > 0$ ,  $\triangleright \sup_{\mathbf{x}_{n+g} \in Y_g(\mathbf{x}_n)} \hat{\sigma}_i(\mathbf{x}_{n+g}) = \infty$ ,  $\triangleright \sup_{\mathbf{x}_{n+g} \in Y_g(\mathbf{x}_n)} |\hat{\mathbf{a}}_i(\mathbf{x}_{n+g})| = \infty$ .

向下 イヨト イヨト

**Theorem 7.** Let  $\hat{\theta}_{n,s}$  be the ML-estimator as before, and  $\hat{\theta}_n(\mathbf{x}_n) = (\hat{\mathbf{s}}(\mathbf{x}_n), \hat{\theta}_{n,\hat{\mathbf{s}}}(\mathbf{x}_n))$  where  $\hat{\mathbf{s}}(\mathbf{x}_n)$  is the optimal number of components according to the BIC. Then  $B(\hat{\theta}_{\bullet}, \mathbf{x}) \ge \frac{g}{n+g}$  for  $\mathbf{x}_n$  so that  $\min_{r < \hat{\mathbf{s}}} L_{n,r}(\theta_{n,r}(\mathbf{x}_n), \mathbf{x}_n) - L_{n,s}(\theta_{n,\hat{\mathbf{s}}}(\mathbf{x}_n), \mathbf{x}_n) > f(g),$ 

f monotonically increasing positive finite function of g.

A B K A B K

**Theorem 7.** Let  $\hat{\theta}_{n,s}$  be the ML-estimator as before, and  $\hat{\theta}_n(\mathbf{x}_n) = (\hat{s}(\mathbf{x}_n), \hat{\theta}_{n,\hat{s}}(\mathbf{x}_n))$  where  $\hat{s}(\mathbf{x}_n)$  is the optimal number of components according to the BIC. Then  $B(\hat{\theta}_{\bullet}, \mathbf{x}) \ge \frac{g}{n+g}$  for  $\mathbf{x}_n$  so that  $\min_{r<\hat{s}} L_{n,r}(\theta_{n,r}(\mathbf{x}_n), \mathbf{x}_n) - L_{n,s}(\theta_{n,\hat{s}}(\mathbf{x}_n), \mathbf{x}_n) > f(g),$ 

f monotonically increasing positive finite function of g.

Analogous result for dissolution point.

A B K A B K

$$\operatorname{BIC}(s) = \sum_{i=1}^{n+g} \log \left( \sum_{j=1}^{s} \pi_j f_{\boldsymbol{a}_j, \sigma_j}(\boldsymbol{x}_i) \right) - (3s-1) \log n.$$

Breakdown by outliers almost impossible!

・ロン ・回 と ・ ヨン・

æ

$$\operatorname{BIC}(s) = \sum_{i=1}^{n+g} \log \left( \sum_{j=1}^{s} \pi_j f_{a_j,\sigma_j}(x_i) \right) - (3s-1) \log n.$$

... but "in-between-liers" may cause trouble. May still often be unstable.

(< ∃) < ∃)</p>

Unclear  $s \Rightarrow$ any fixed s method breaks down.

Э

Conclusion

Add more points than size of smallest cluster: any fixed s method breaks down (on any dataset).

Conclusion

Add more points than size of smallest cluster: *any* fixed *s* method breaks down (on any dataset). Estimated *s*: add clusters to avoid these problems.

### So do we just have to estimate s then?

(... and not worry about noise, trimming etc.?)

・ロン ・回 と ・ ヨン・

# So do we just have to estimate s then?

(... and not worry about noise, trimming etc.?)

May have to fit lots of clusters if many isolated outliers are present.

Computation & interpretation difficult.

# So do we just have to estimate s then?

- (... and not worry about noise, trimming etc.?)
  - May have to fit lots of clusters if many isolated outliers are present.

Computation & interpretation difficult.

 May rather want points classified as "noise" for reasons of interpretation.

### "Death by flexibility"

mclustBIC solution.

Christian Hennig Some thoughts about robust clustering

æ

## "Death by flexibility"

mclustBIC solution.

No lower bound for cov-eigenvalue specified in mclustBIC. One-point cluster degenerates L with flexible cov-matrix. Therefore, outlier changes cov-matrix model.

### 5. Tuning constants

- Flexible cov-matrices: need lower bound for cov-matrix eigenvalue.
- Trimming methods need trimming rate.
- Improper noise method needs noise level c.

These tune robustness behaviour as well.

・ロト ・回ト ・ヨト ・ヨト - 三

Conclusion

How many points are needed to form a "cluster", not a "group of outliers"? (May depend on how packed they are.)

Conclusion

Rather separate non-well separated clusters? (May depend on what's added.)

#### Conclusion

Large-variance: cluster or outliers?

くヨン

#### Conclusion

Large-variance: cluster or outliers?

No proper robustness assessment without decision about what we want a method to do. In CA we don't *want* 0.5 or 0.3 breakdown point,

### Current work on improper noise (Coretto & Hennig)

**Idea:** fit noise so that remaining points are "good mixture" (see also Gallegos & Ritter 2005;  $\chi^2$ /Mahalanobis)
